The STELLA facility is a collaboration of the AIP with the IAC.
It is funded by the Science and Culture Ministry of the German State of Brandenburg (MWFK) and the German Federal Ministry for Education and Research (BMBF).

Outline

- The STELLA observatory
- WiFSIP core science - SOCS
- SES core science - time series DI

STELLA

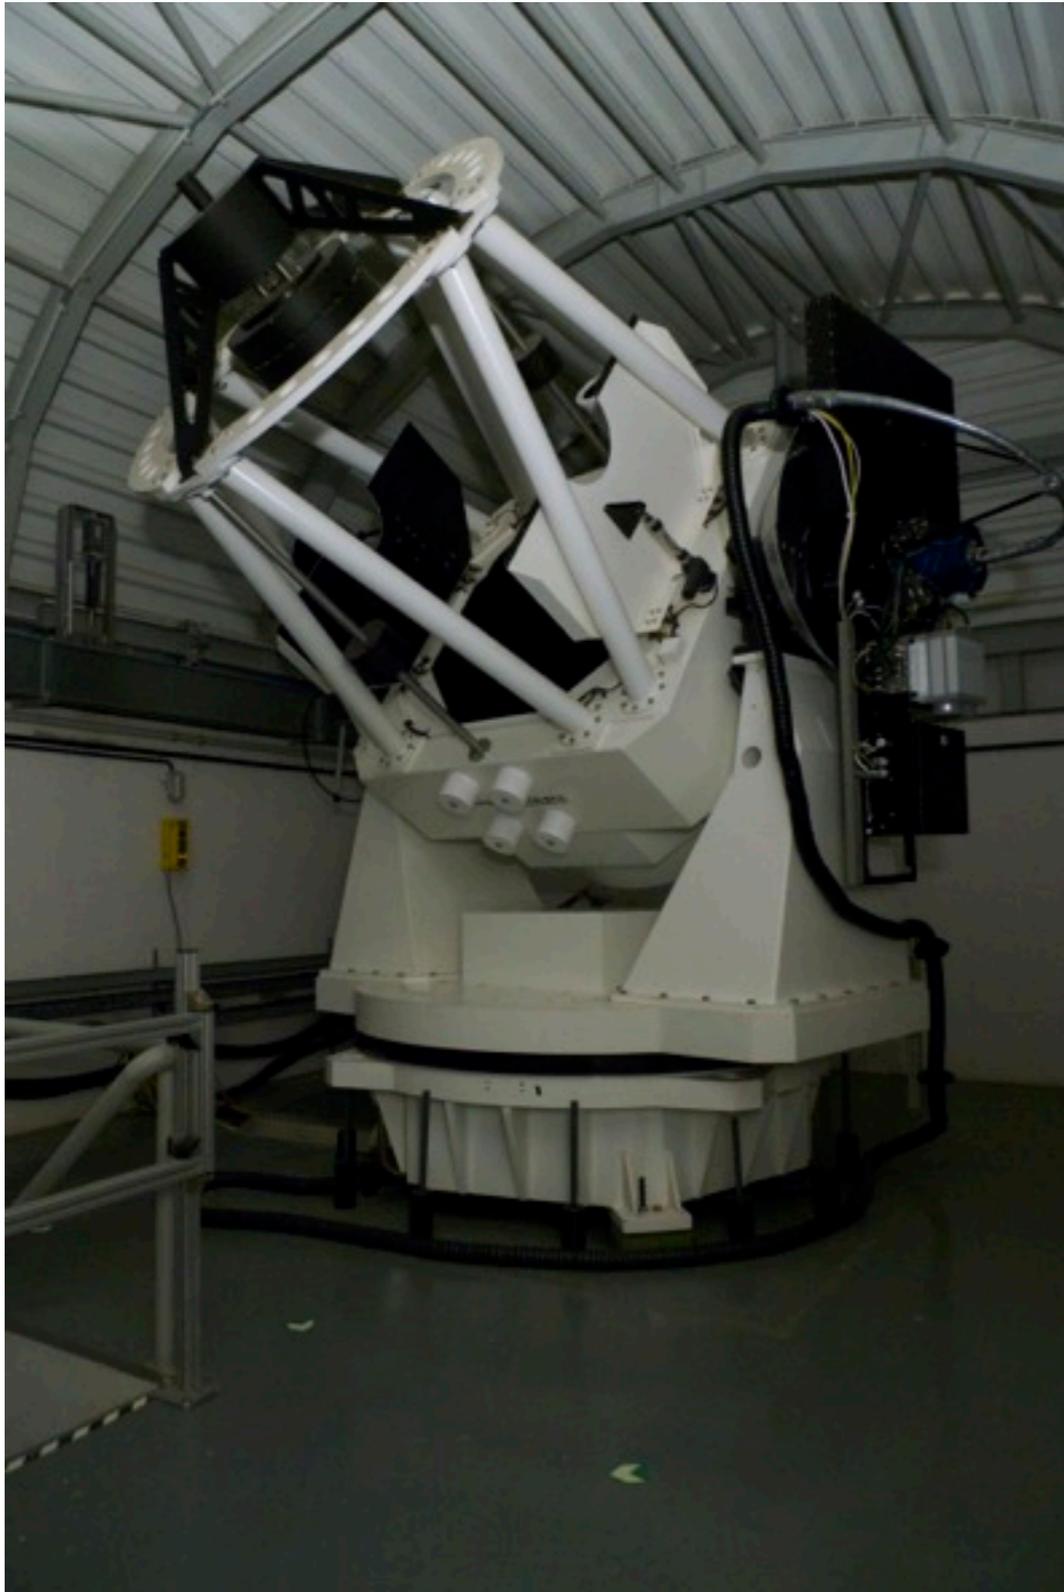

- A project for monitoring Stellar Activity
- Focus on observations with long time-lines (solar activity cycle is 22 years)
- High-resolution spectroscopy for Doppler imaging (resolving surface structures on rapidly rotating stars)
- Wide-field imager for photometric studies of active stars
- „SOCS“: STELLA open cluster survey: rotation periods & stellar parameters of stellar clusters vs. age
- Keep it simple: One instrument per telescope
- Mostly routine tasks, should be highly automated. No personal on site, automatic observations and data reduction.
- Should be able to accommodate special needs, e.g. targets of opportunities (GRBs), planetary transits, etc.

The STELLA observatory

- Located at Teide observatory, Tenerife, $16^{\circ}30'35''$ W $28^{\circ}18'00''$ N, 2400m altitude
- Two telescopes in common enclosure, each with dedicated instrument
- Own weather stations, dust meter, cloud monitor for protection of the instruments

STELLA/WiFSIP

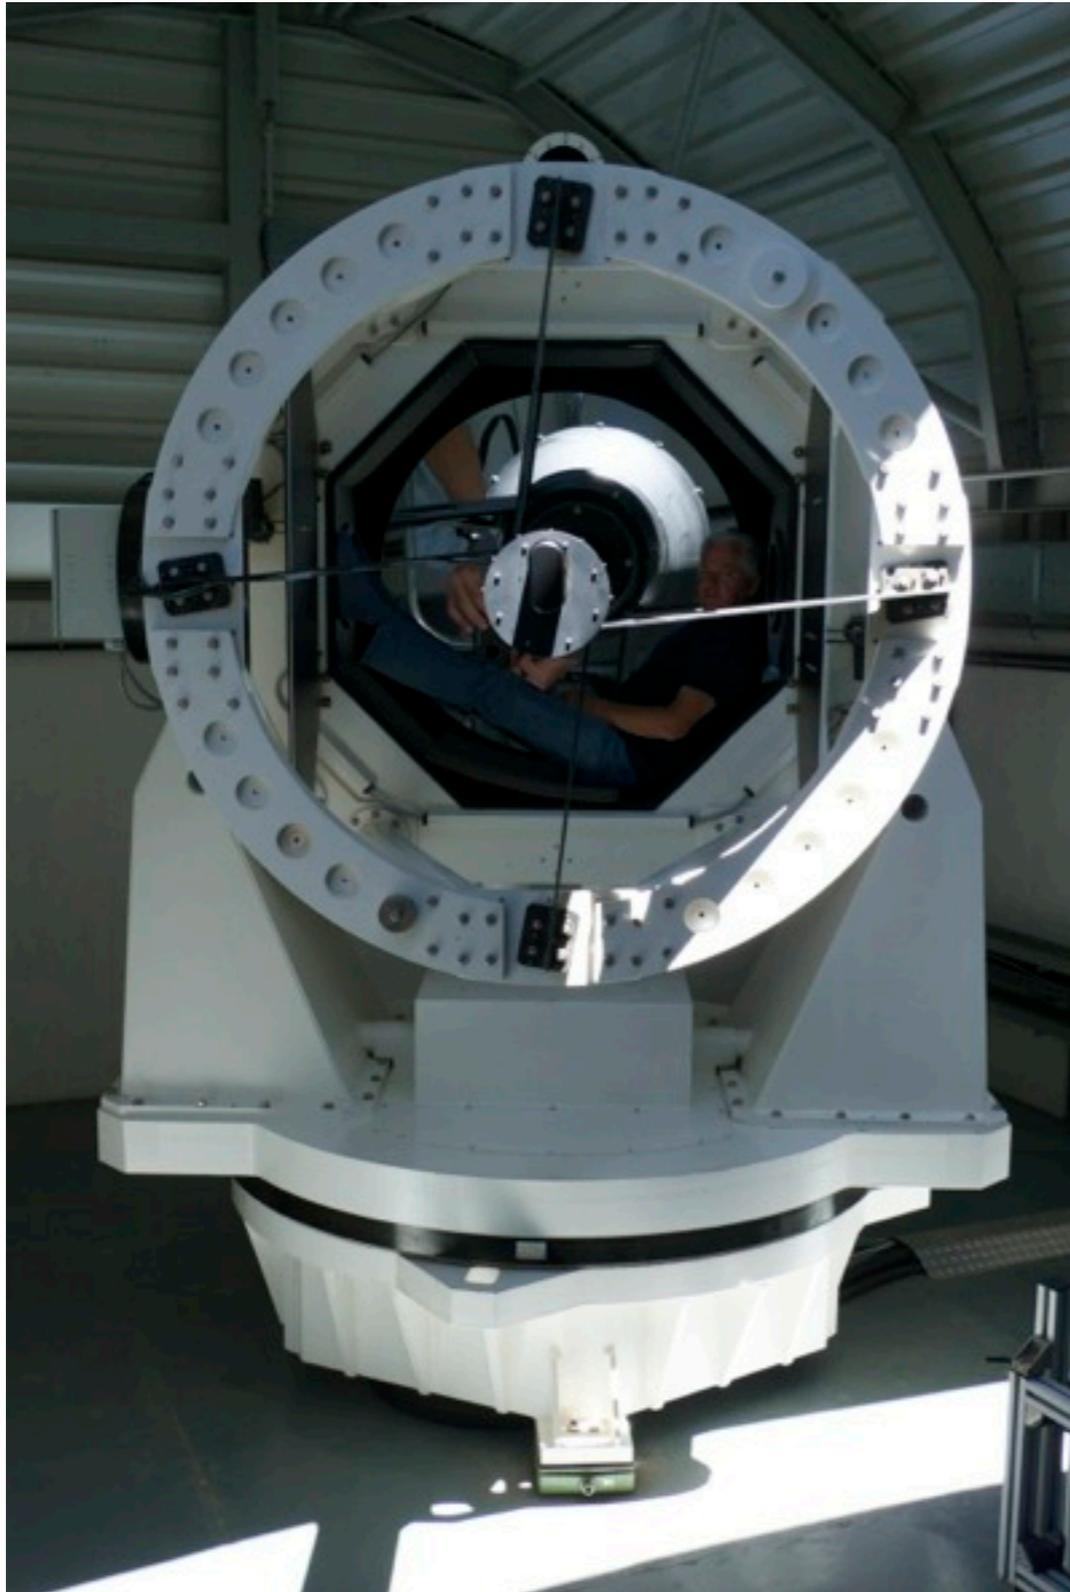

- STELLA-I telescope: 1.2m aperture, Alt/Az, Cassegrain f/8, 2 Nasmyth ports (fiber feed & imaging instrument)
- Acquisition & Guiding with auxiliary telescope (off-axis in preparation)
- Wide Field STELLA imaging Photometer (WiFSIP), 22' FOV
- Full Johnson/Sloan/Stromgren/H α filters
- 4kx4k, 15 μ m, STA400 CCD detector, Magellan CCD controller with 15 s full-frame readout (4 amplifiers)
- Detector update coming soon (better cosmetics and thus better flat-field accuracy)

STELLA/WiFSIP

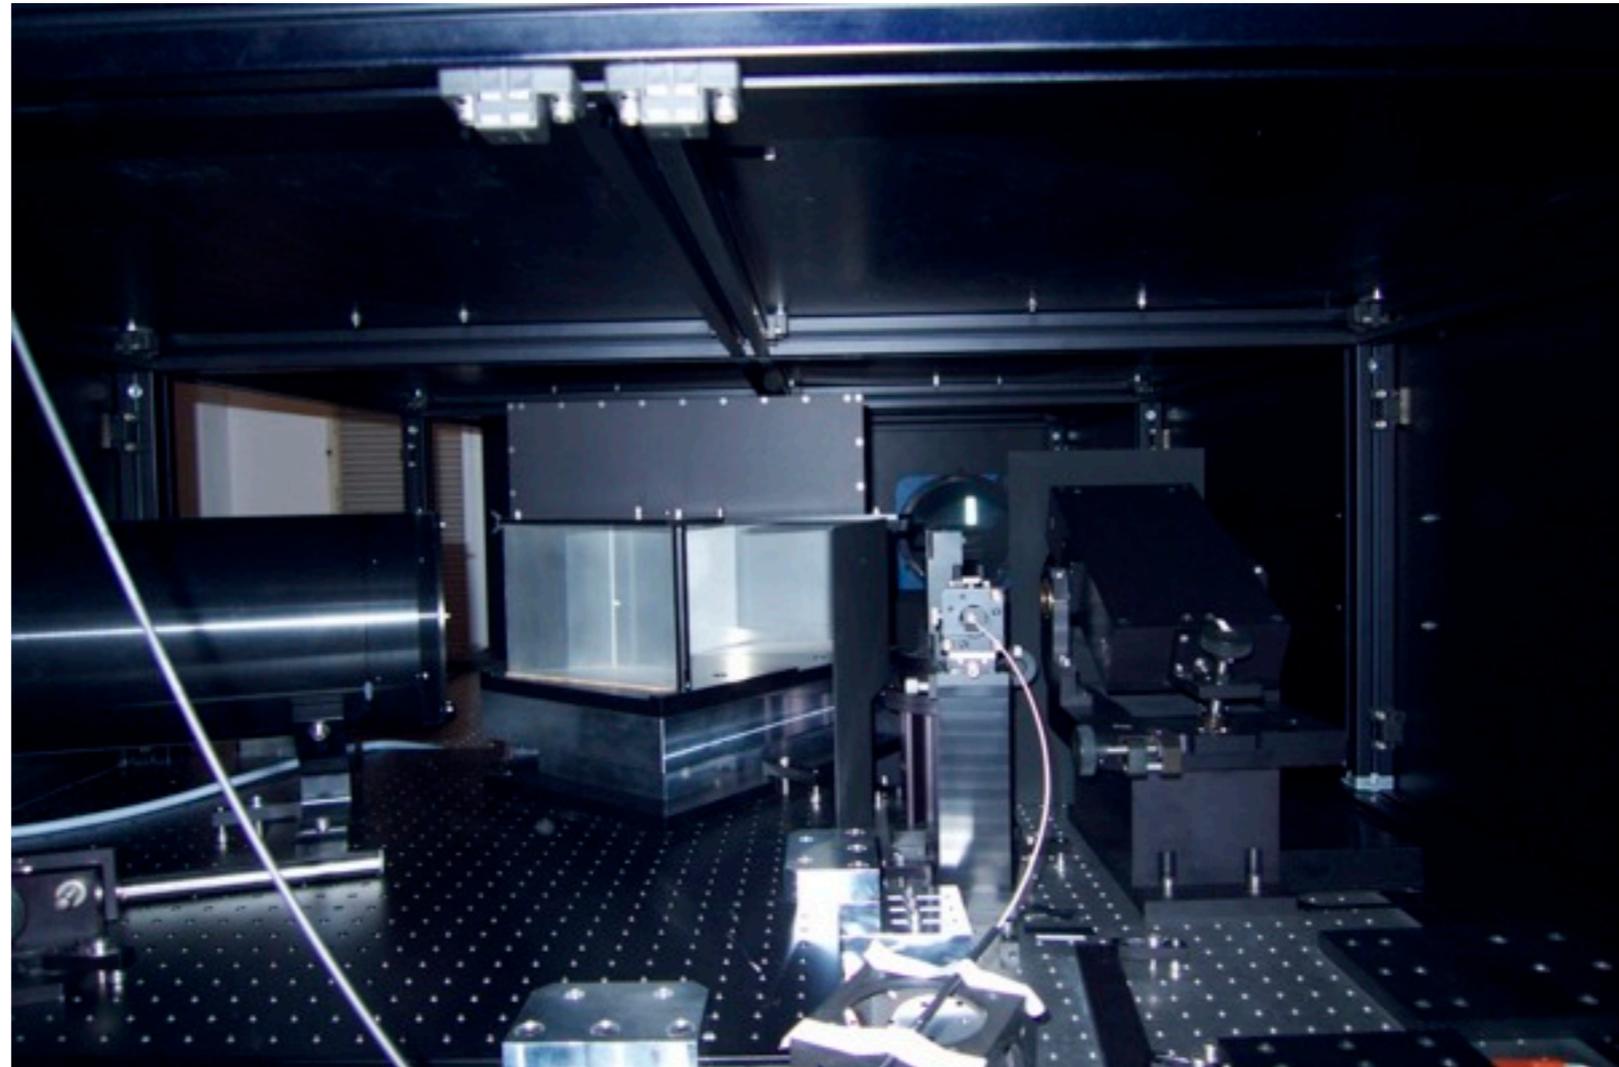

- NGC 7092, exposure time 40 s in Sloan r' (June 16, 2010)
- flat-fielding is the biggest headache currently (CCD)
- takes 2 days (2x morning, 2x evening twilight) to do flat fields in all filters
- Self-illuminating flat-field screen being tested at the 80cm RoboTel at AIP
- CCD has many wavelength sensitive coating defects, prohibits sub-mmag photometric accuracy

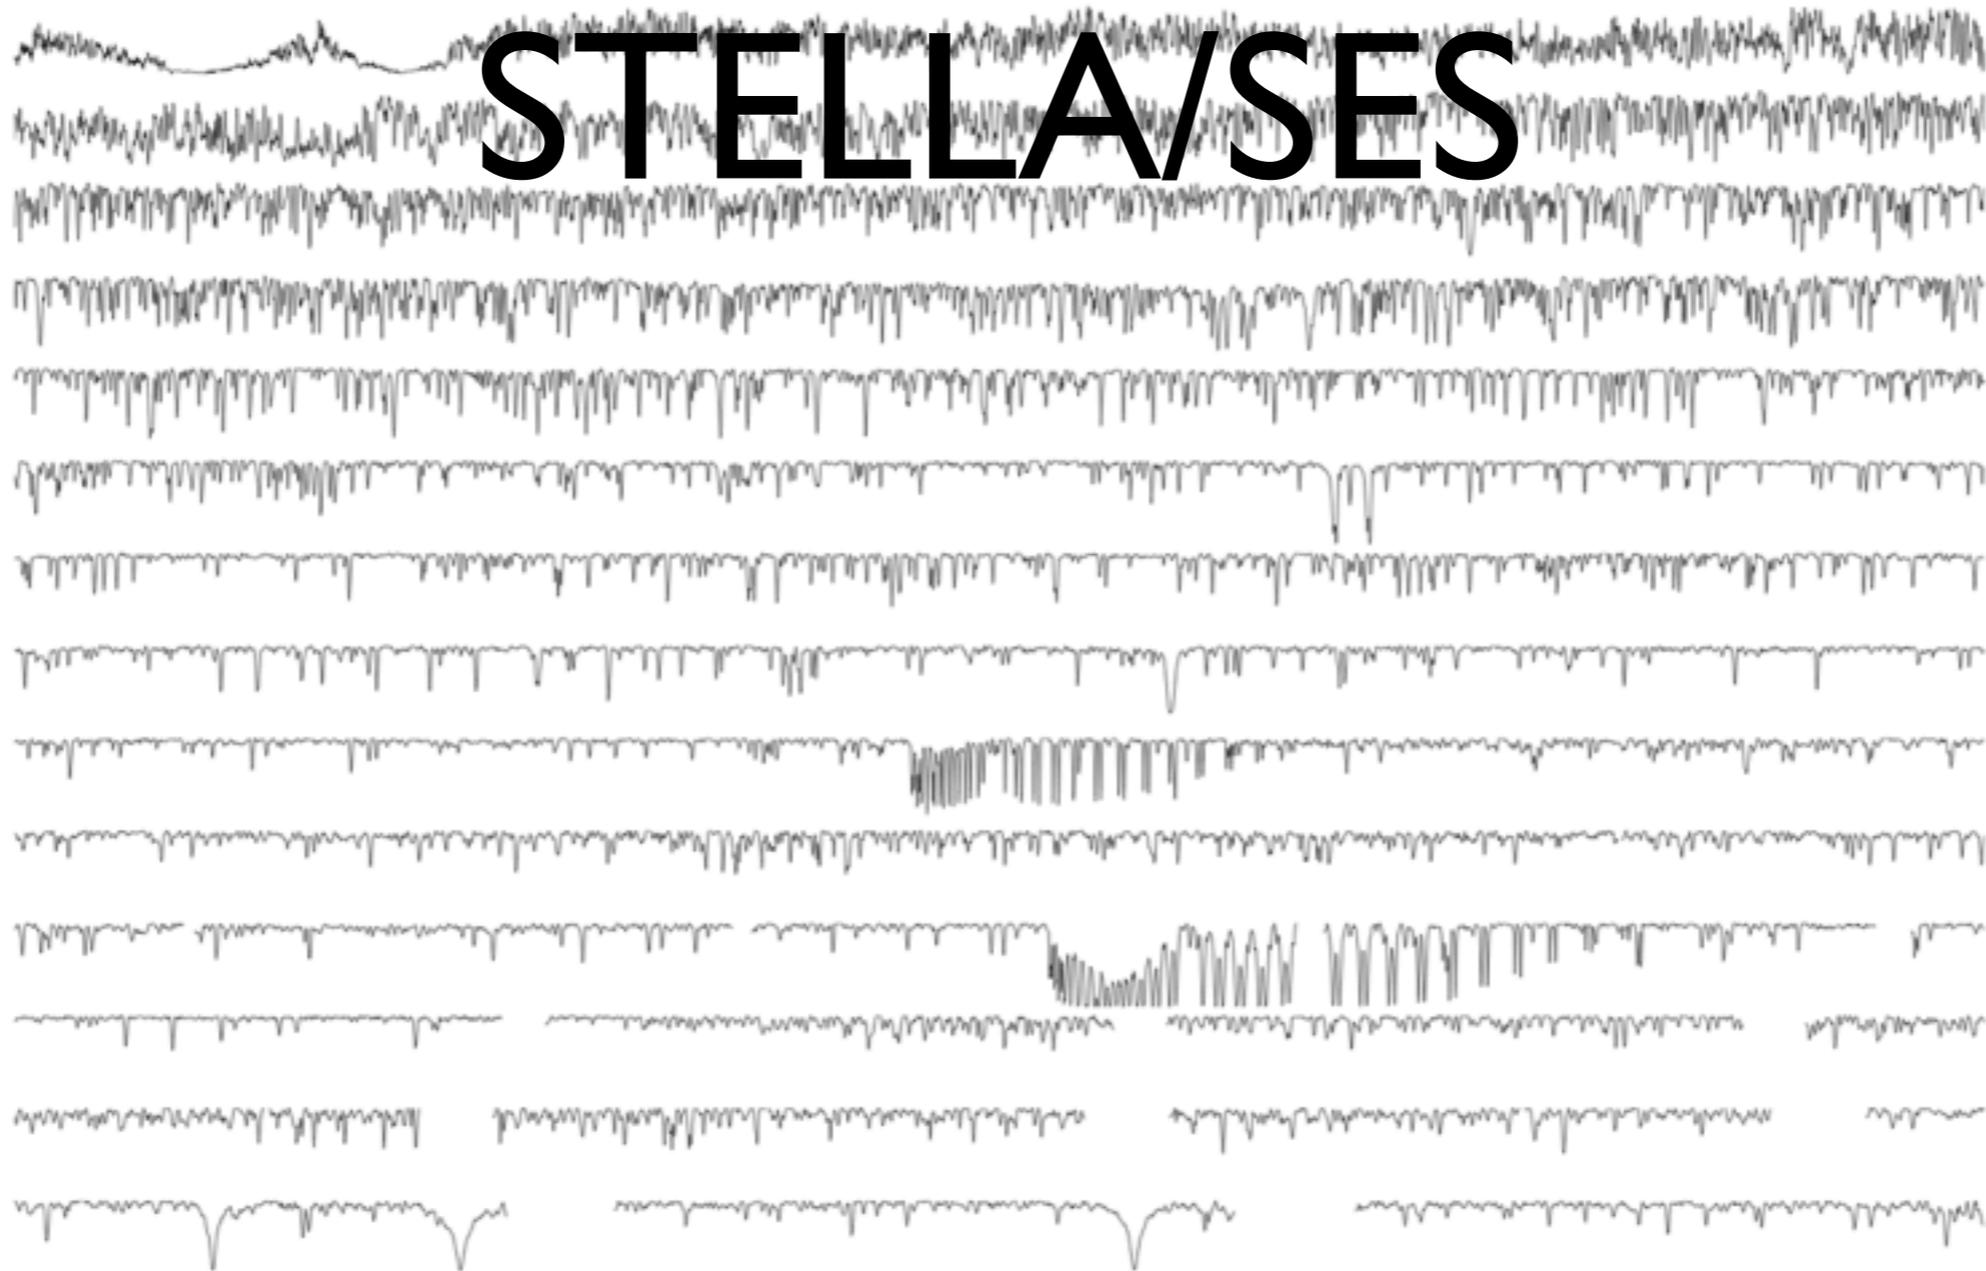

STELLA/SES

- STELLA-II telescope: 1.2m aperture, Alt/Az, spherical primary, prime-focus corrector $f/8.4$,
- Acquisition with auxiliary telescope
- Fine-acquisition & guiding with fast industrial firewire camera on $140\mu\text{m}$ pinhole mirror (in the future only acquisition)
- 4 fixed ADCs
- Fiber feed for STELLA échelle spectrograph (SES) using $50\mu\text{m}$ fiber with $r=167\mu\text{m}$ lens at prime focus ($\approx 3''$ on sky aperture)
- Image slicer coming soon, then using $200\mu\text{m}$ pinhole and $72\mu\text{m}$ fiber

STELLA SES

- Bench-mounted échelle spectrograph, $R=55,000$, 390 to 870nm wavelength coverage
- Temperature controlled room, SES inside an insulated box in that room
- 45s readout for 4-channel 4kx4k CCD using AIP-built Magellan controller
- coming soon: 2-way slicer + simultaneous calibration spectrum on each exposure

Full spectrum of HD 1 using the old optical camera & CCD detector (hence the inter-order gaps on the red end)

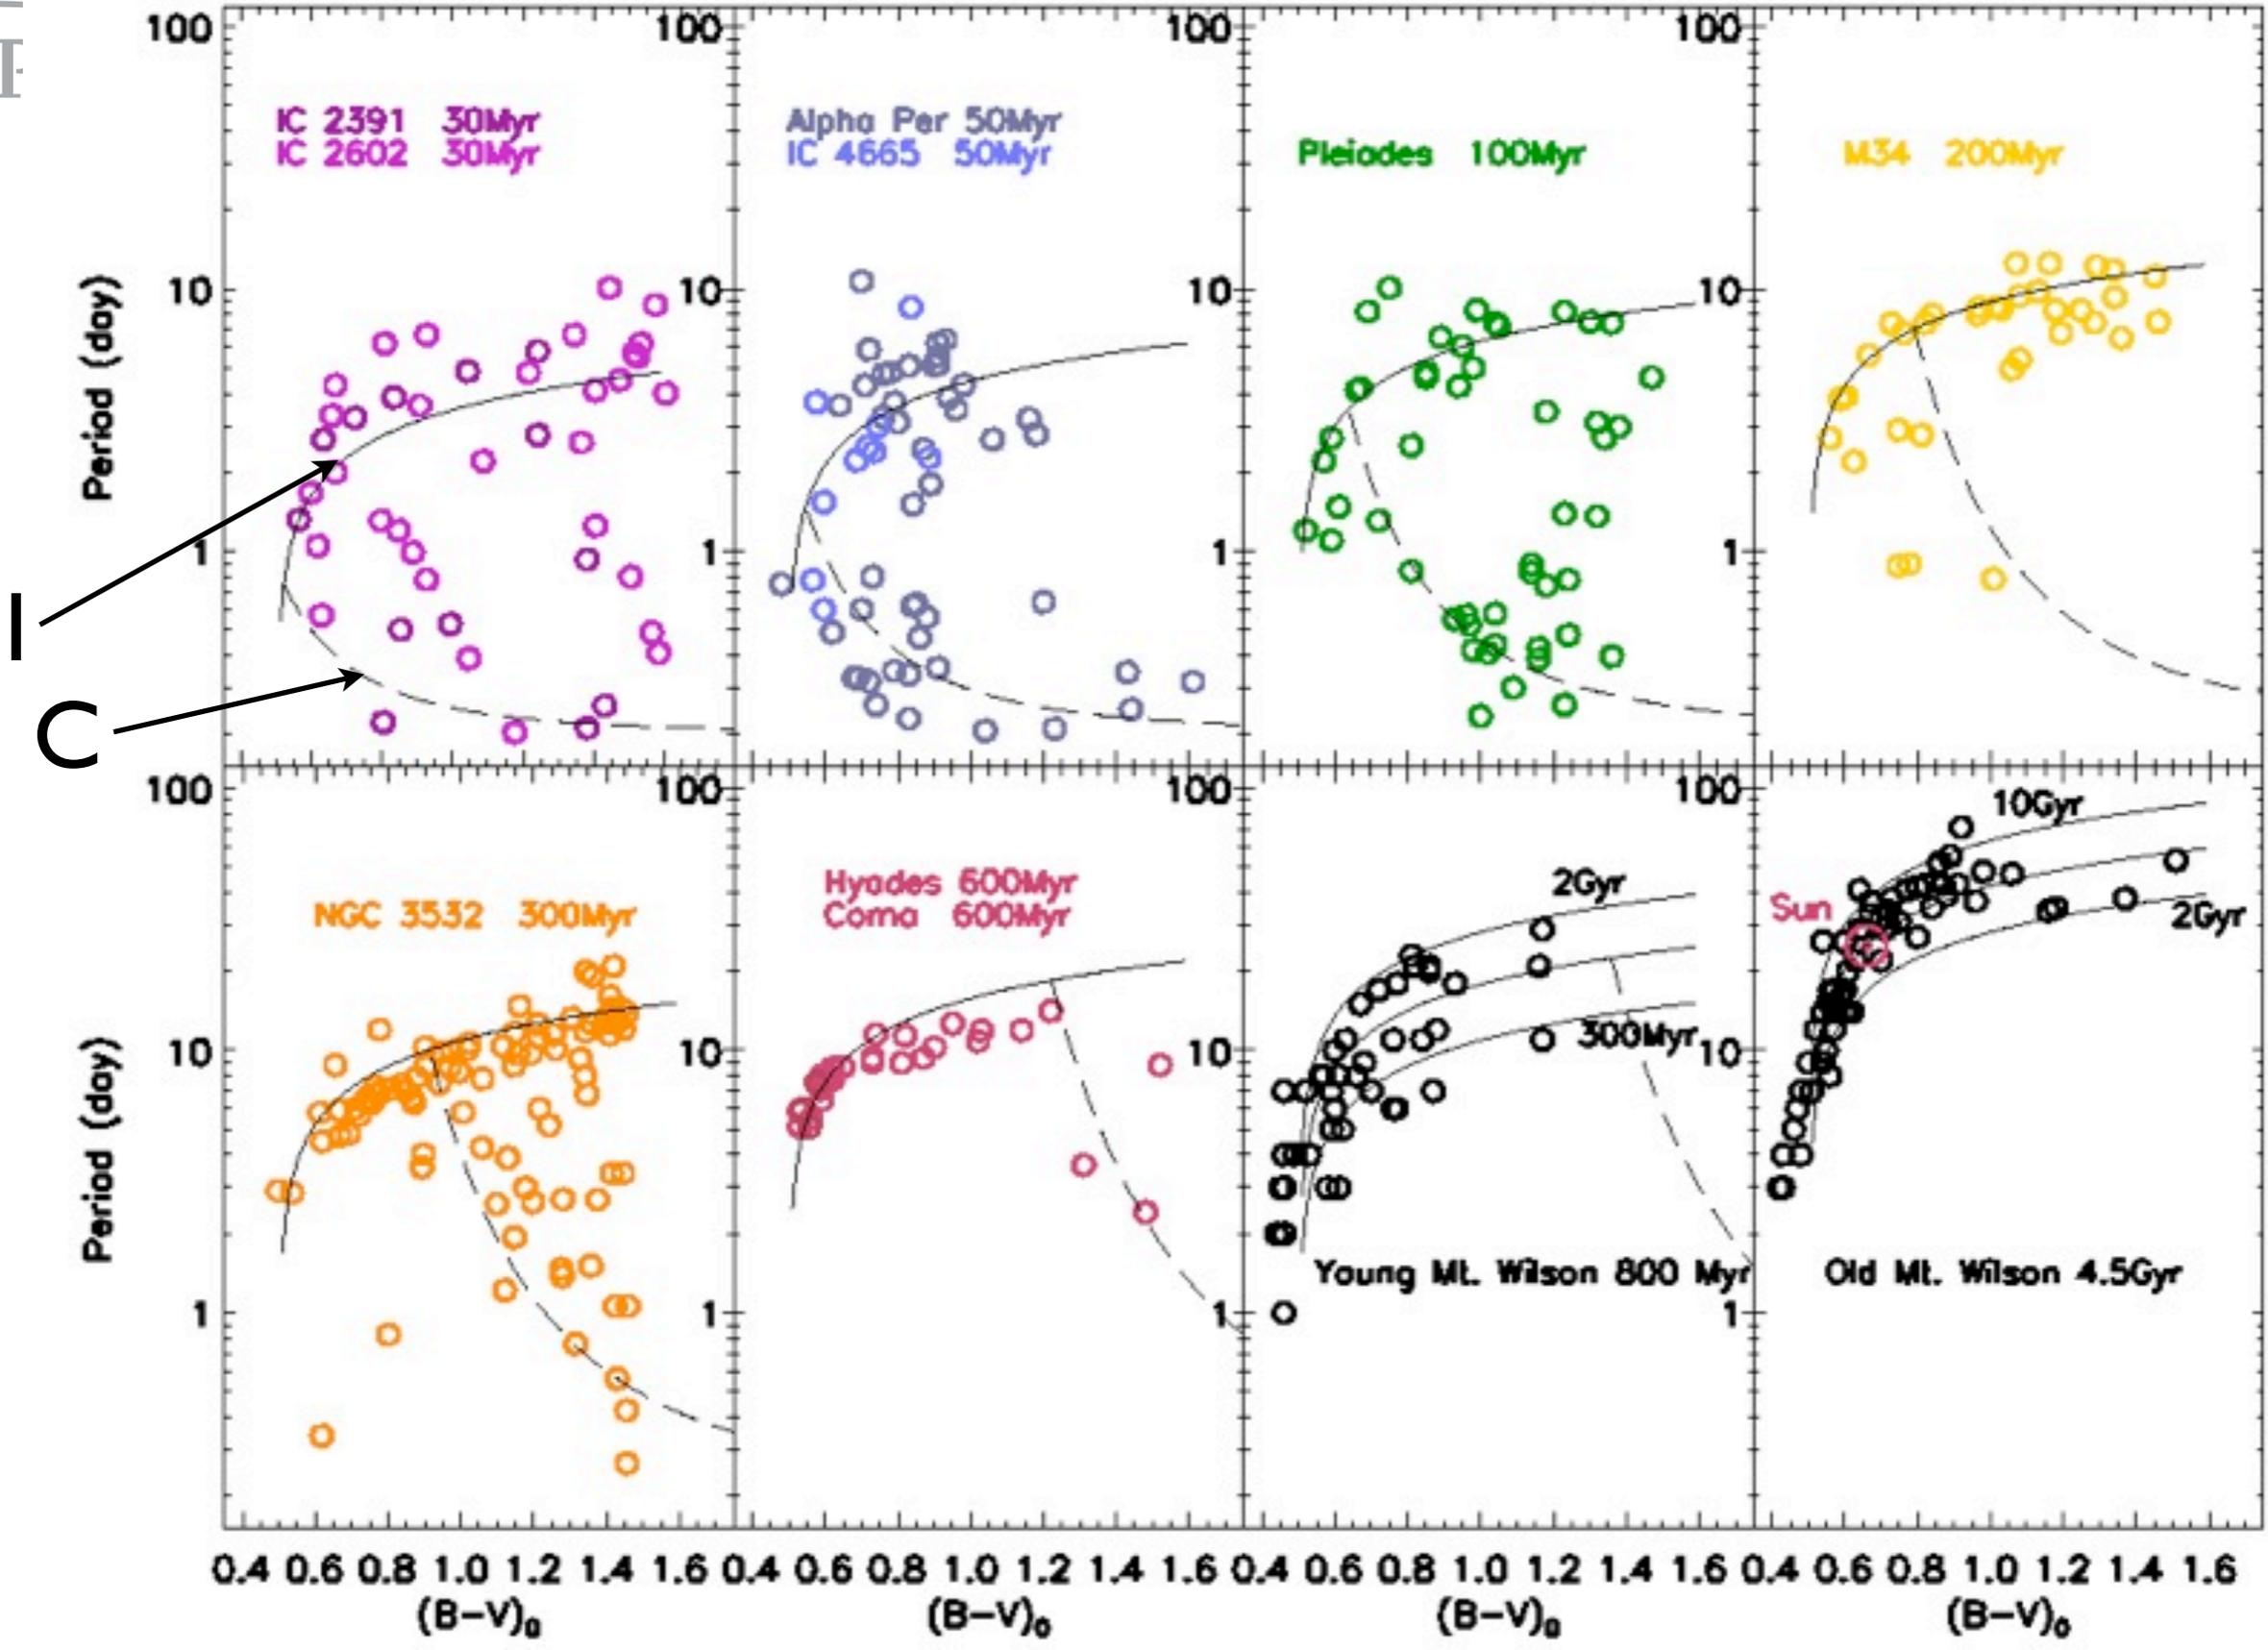

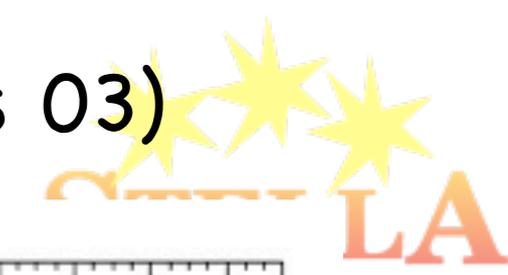

WiFSIP Core science

- Main advantage of robotic telescopes is the time domain
- Combining Stellar Activity & Time series
- STELLA open cluster survey:
 - ➔ Rotational Periods of open cluster stars
 - ➔ Age sequence of clusters delivers $\Delta P/\Delta t$

Outside of cluster-seasons general proposals like planetary transits.

Heuristic interpretation of C-P diagrams (Barnes 03)

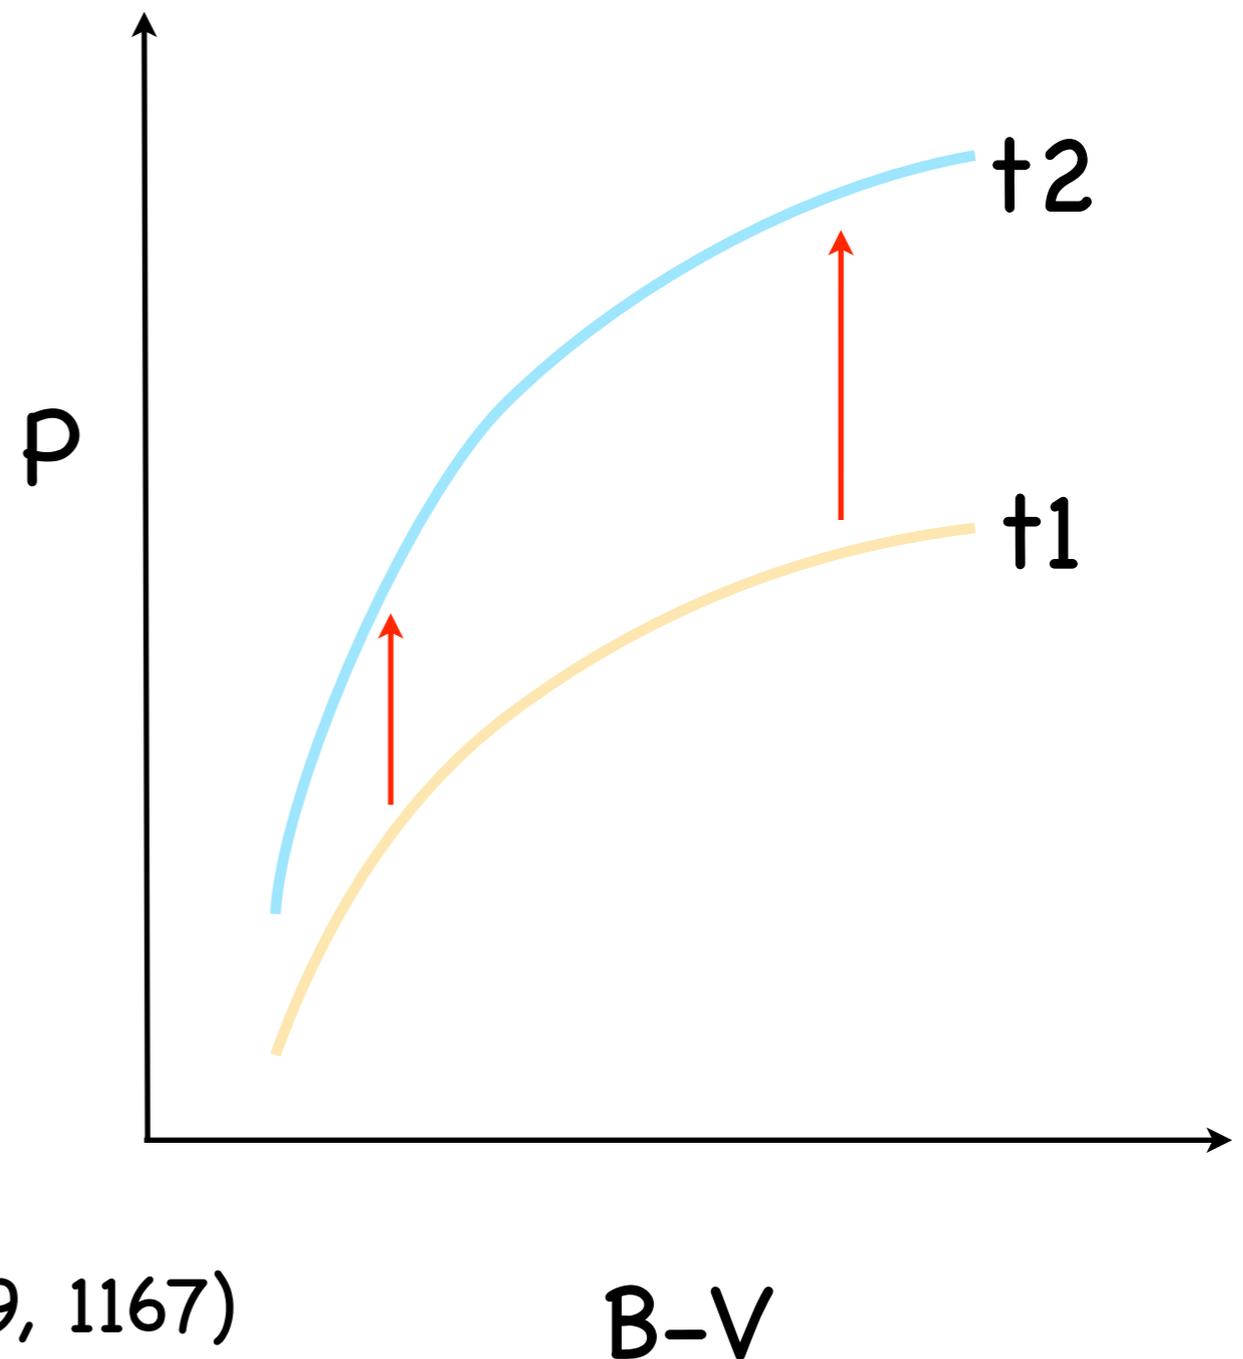

I-type stars spin down Skumanich-style

$$P_I(B - V, t) = f(B - V) \cdot g(t)$$

$$g(t) = \sqrt{t}$$

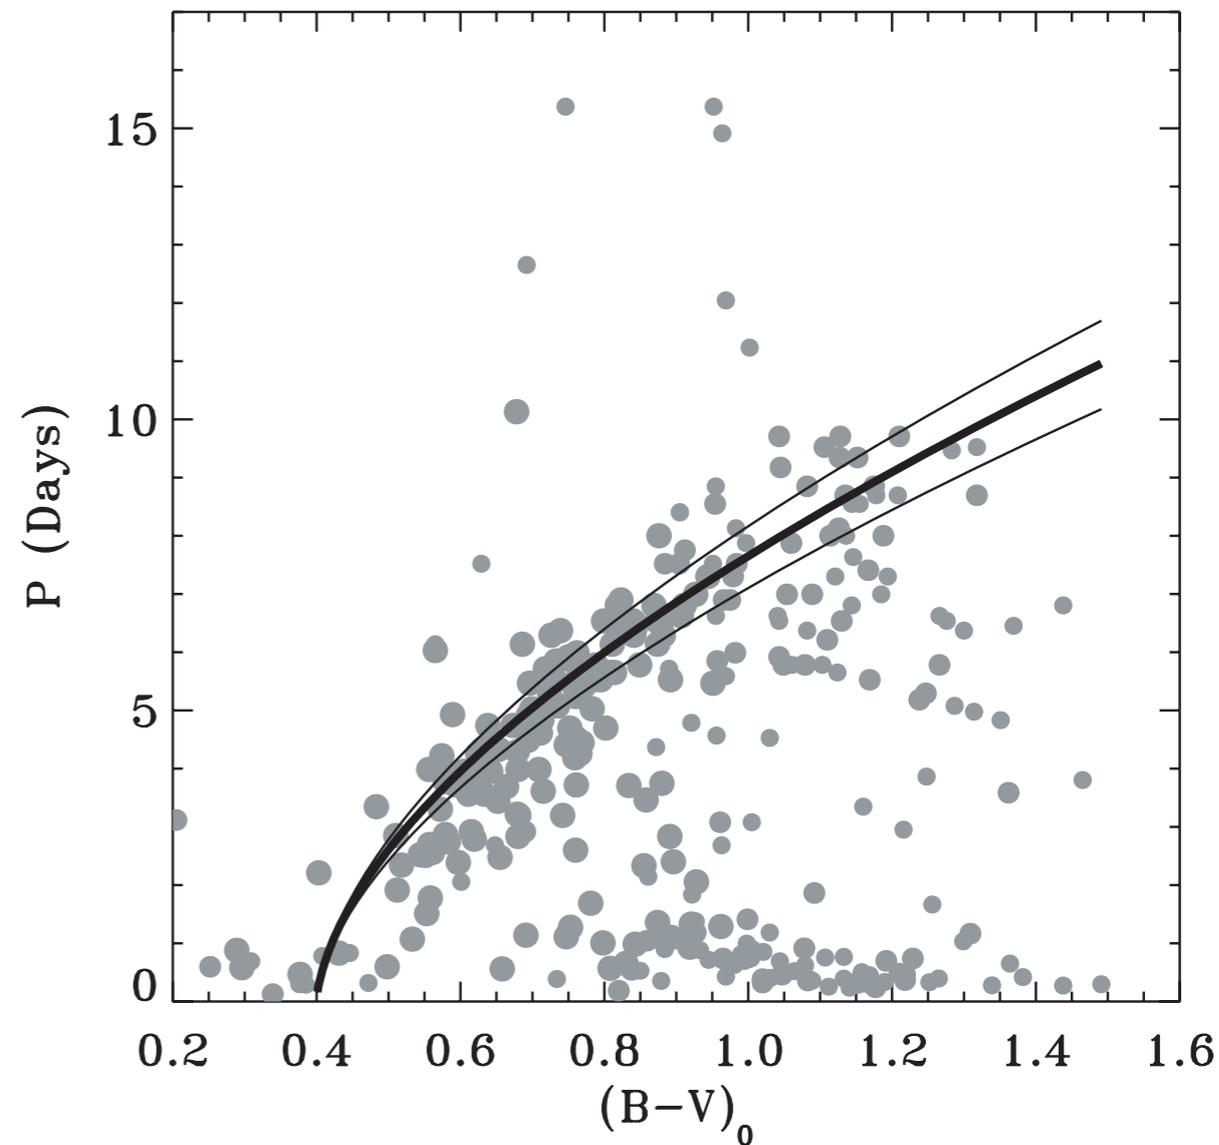

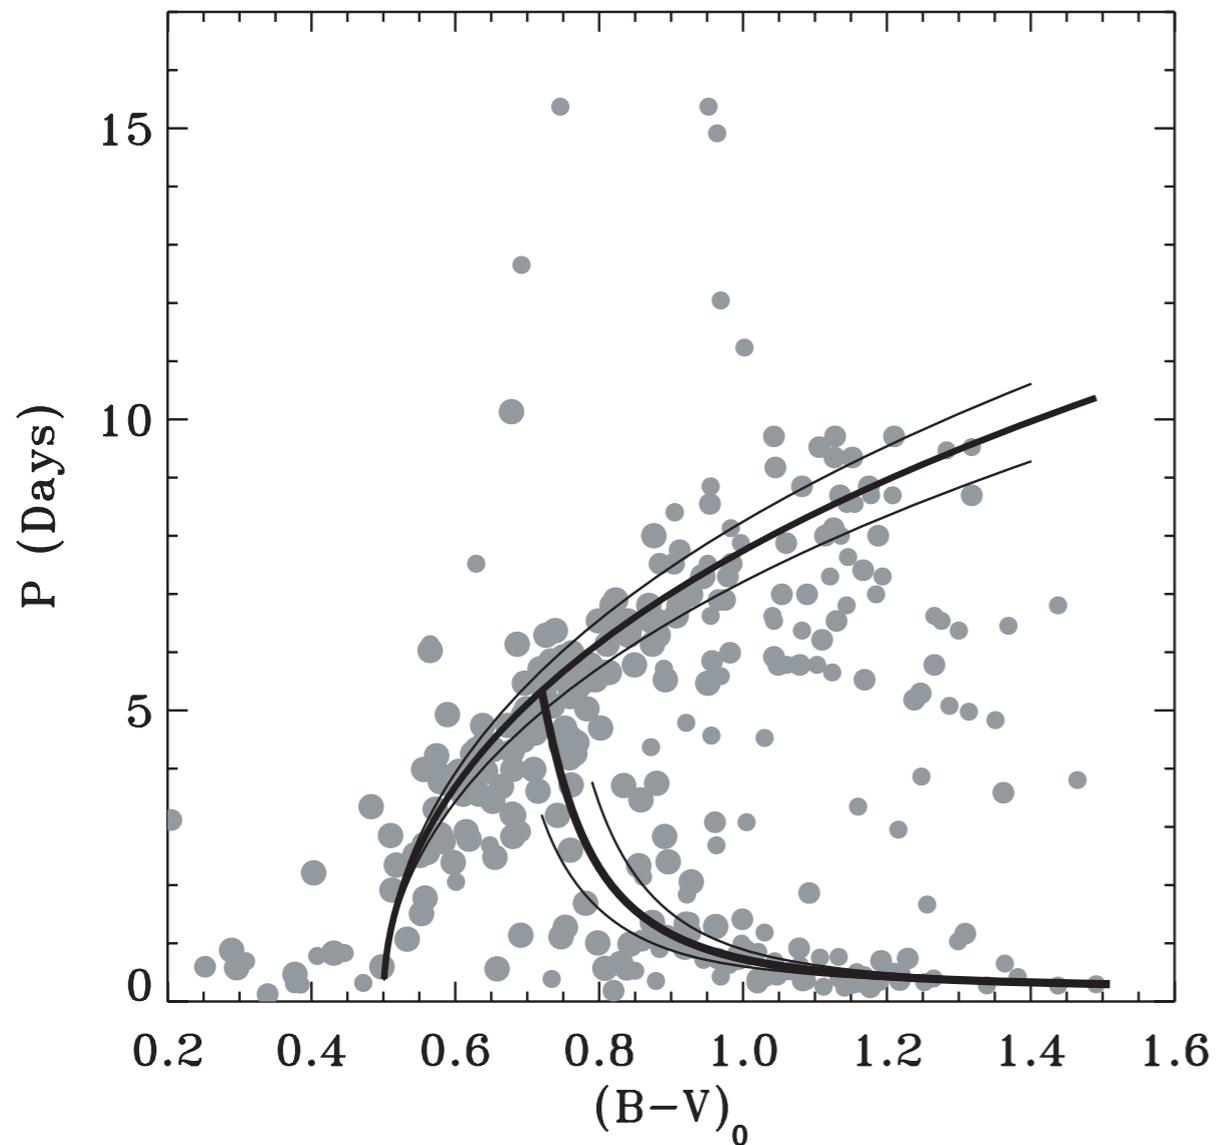

$$f(B - V) = a(B - V - c)^b$$

$$a, b, c = 0.778, 0.519, 0.4$$

(Barnes 2007, ApJ, 669, 1167)

e.g. M35

Barnes 2003/2007 age/rotation relation for 130/150/170 Myrs together with M35 data
(Meibom et al. 2009)

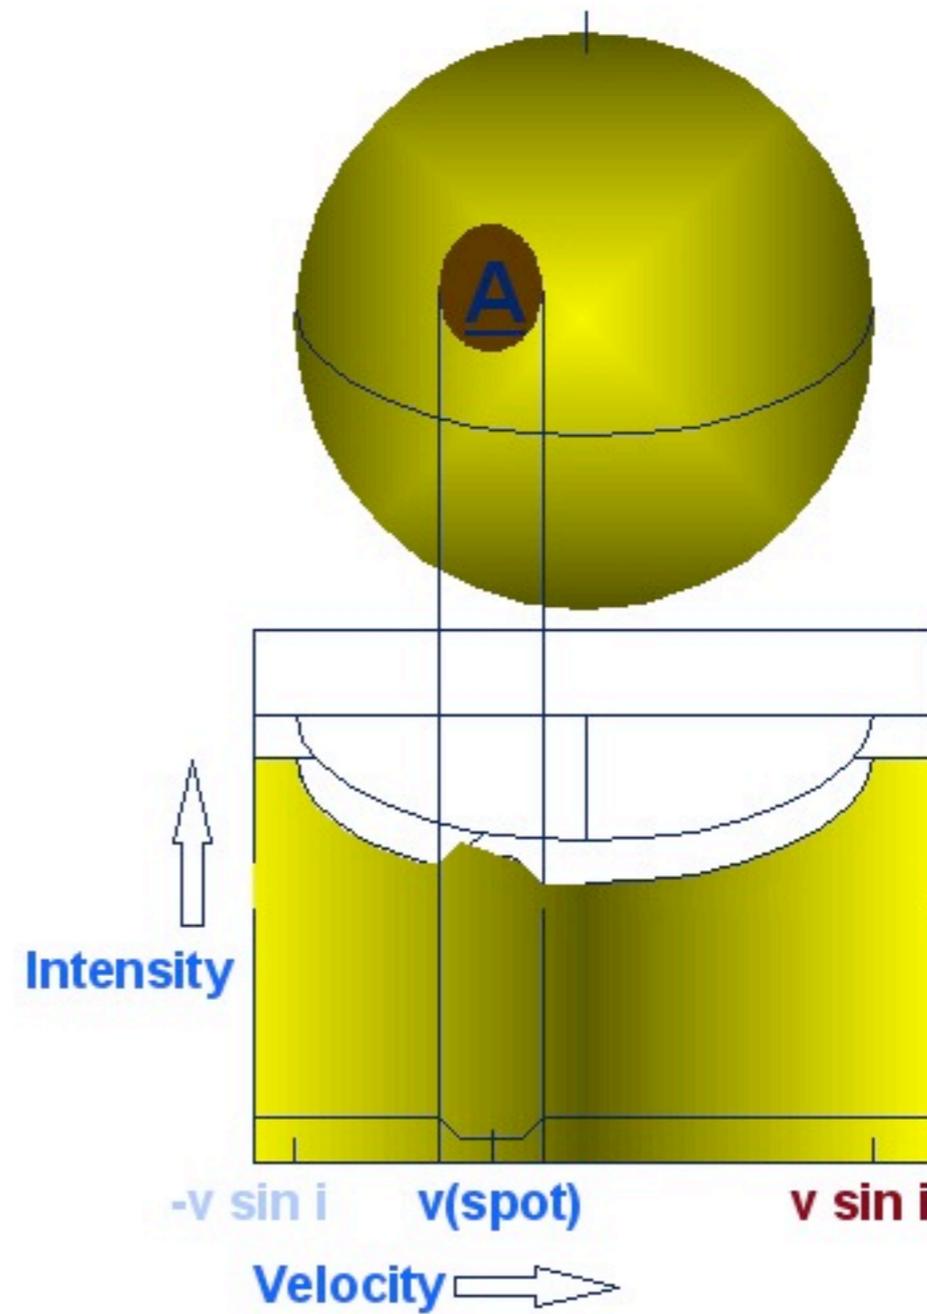

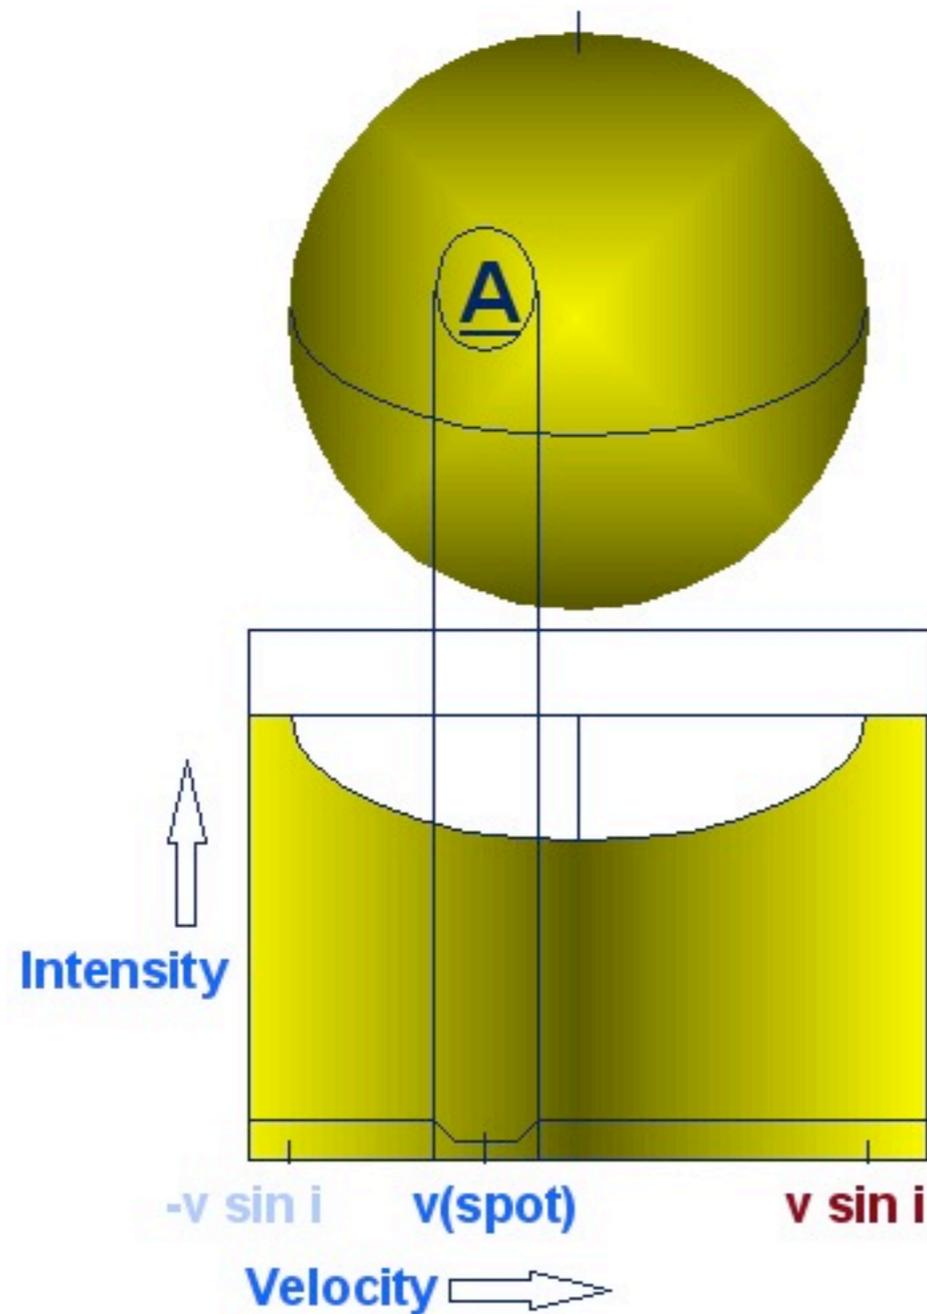

SES Core science

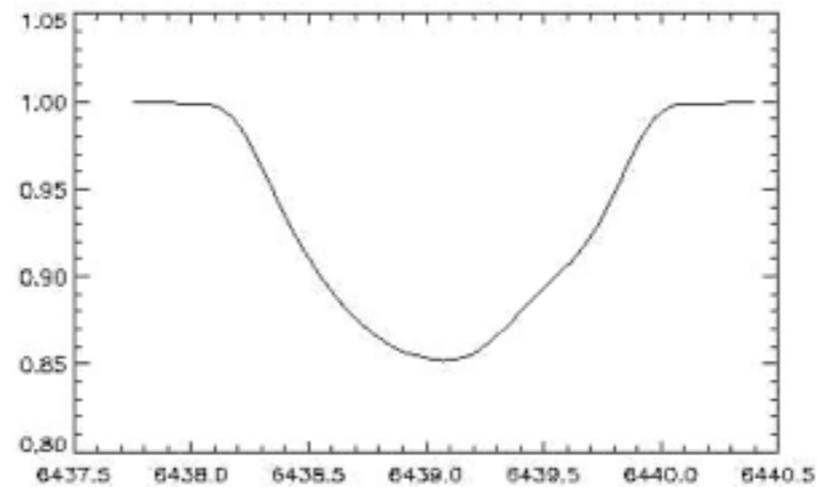

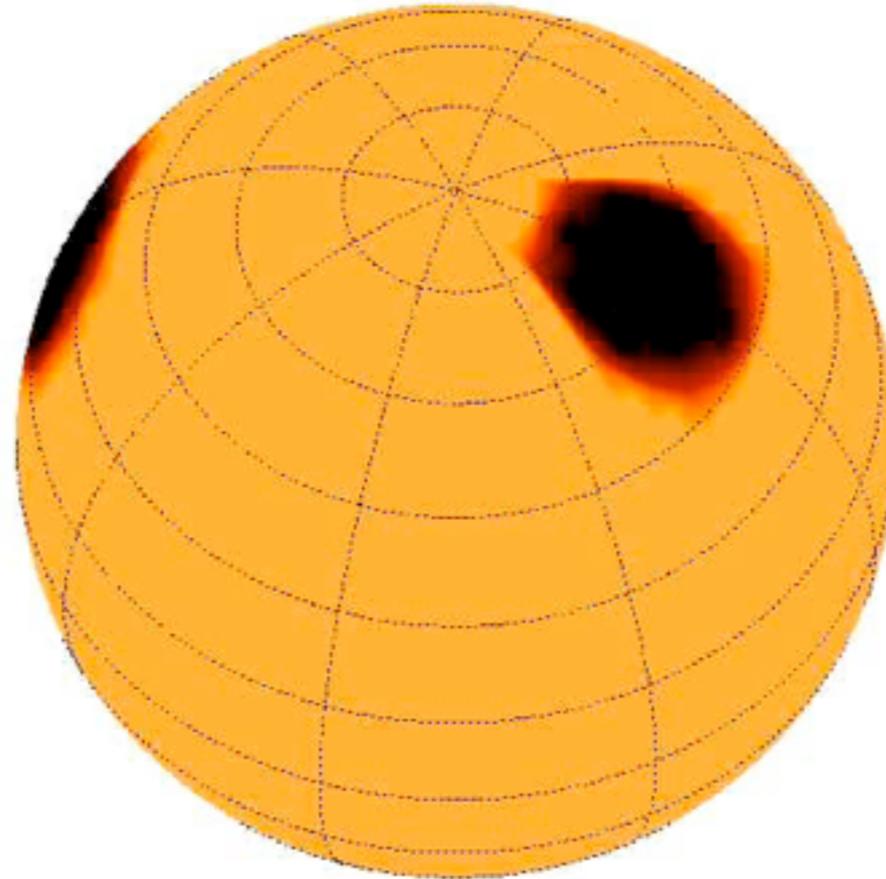

- Main advantage of robotic telescopes is the time domain
- Solar Activity has 11/22 year cycle period
- Time series Doppler imaging

Rest of the time various projects like support of space or large telescope proposals, binary stars, cepheids, planetary transits,...

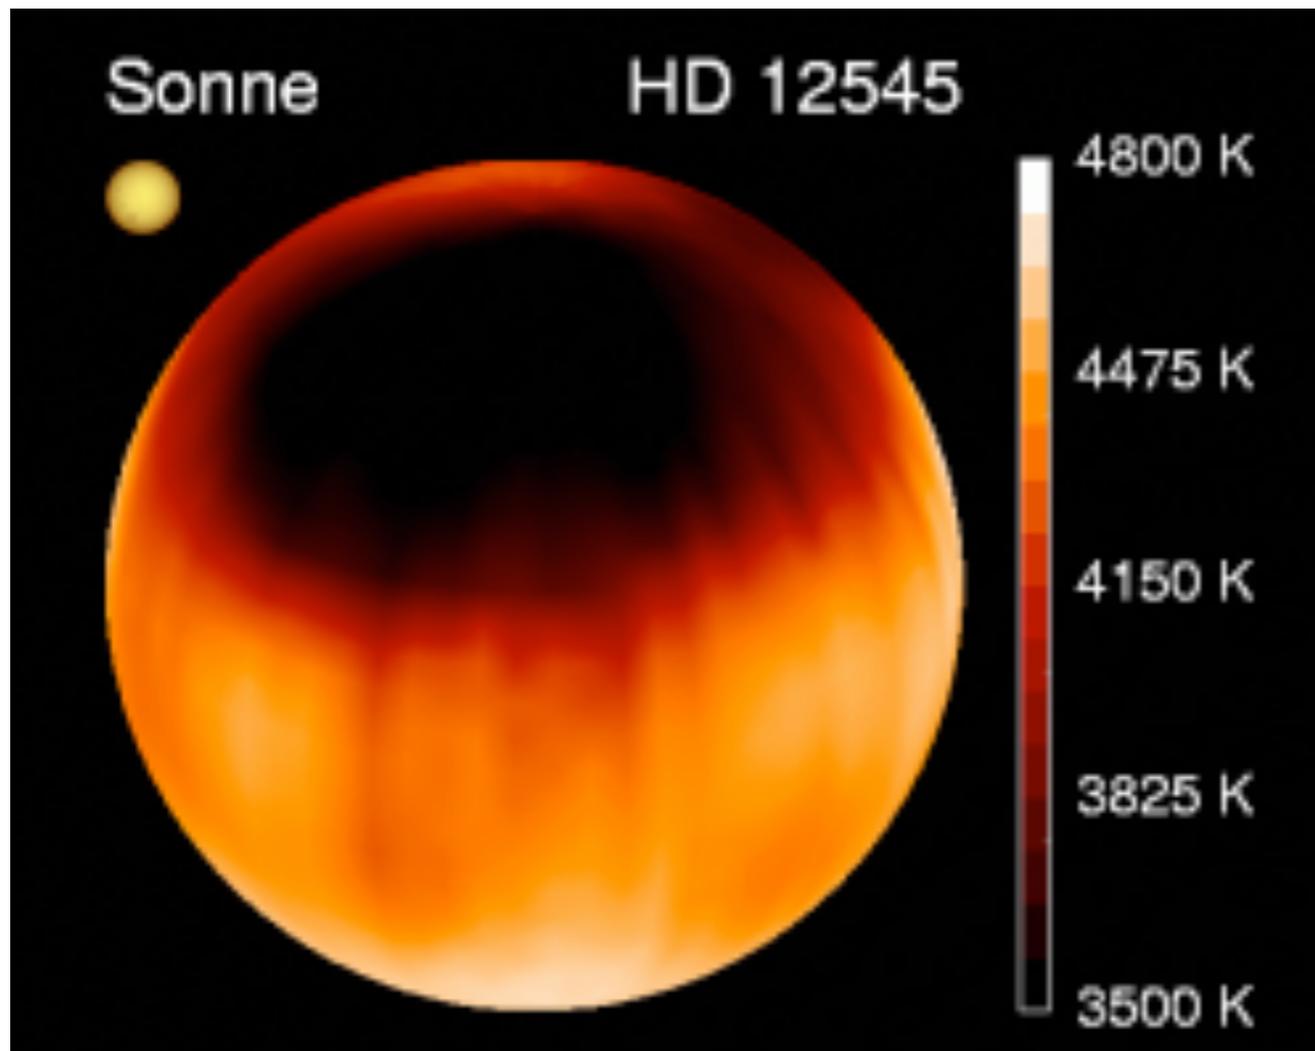

Doppler imaging

Doppler imaging

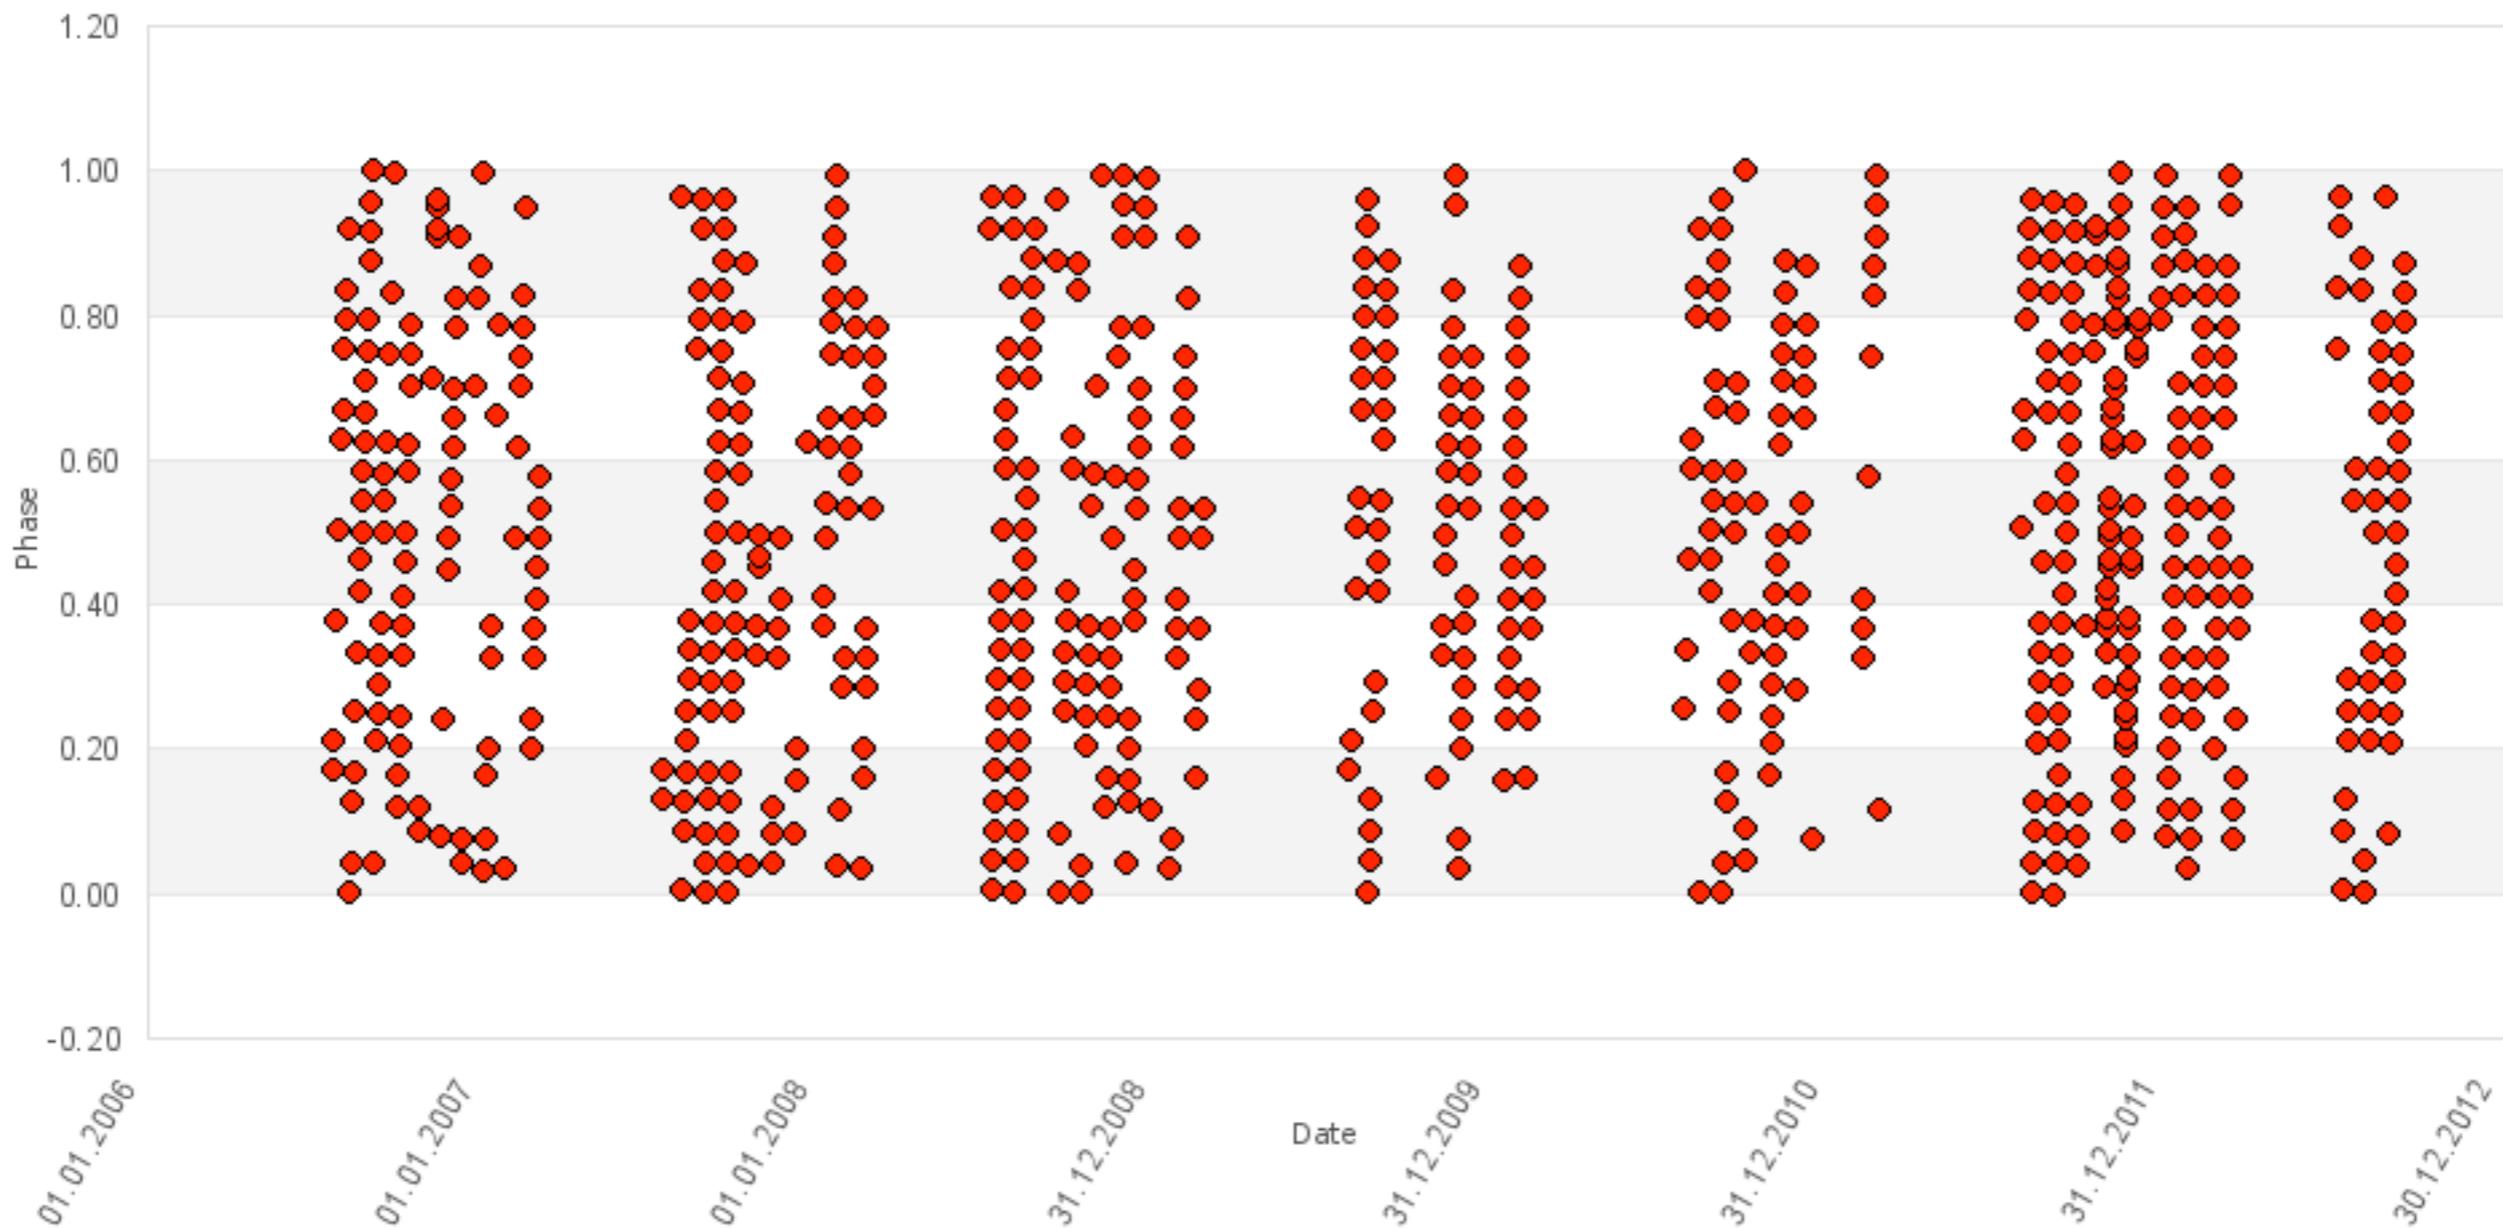

XX Tri

Strassmeier et al. 1999

- very active red giant
- 20 days period
- Observed once a day when possible
- aim is to get dynamic parameters: cycle period, differential rotation, spot decay rates (these are ingredients for dynamo/MHD calculations)
- PhD thesis A. Künstler

HIP 9630

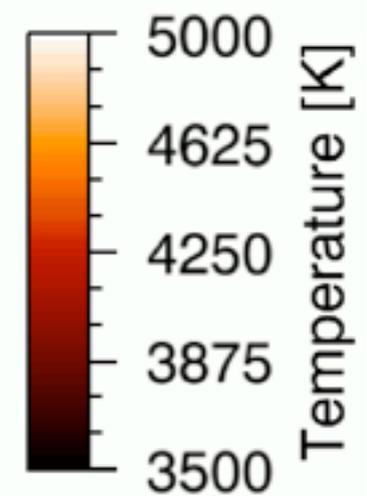

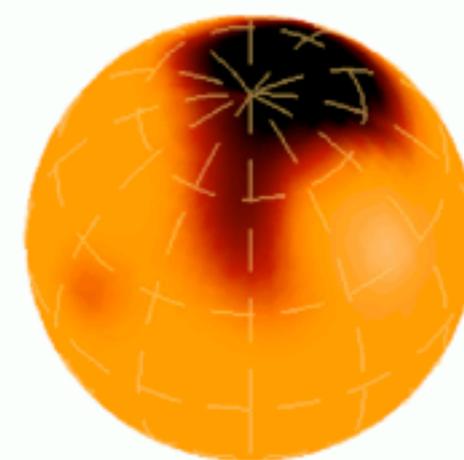

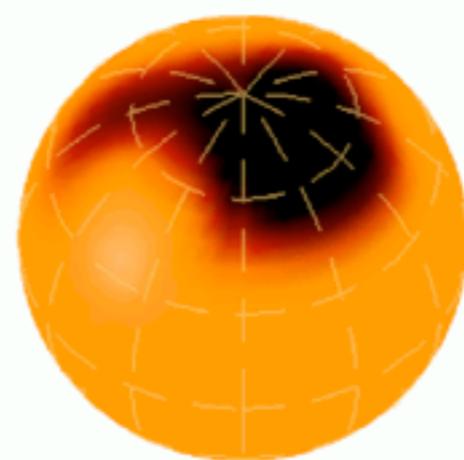

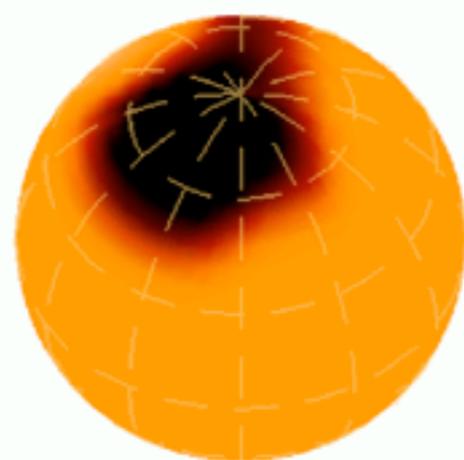

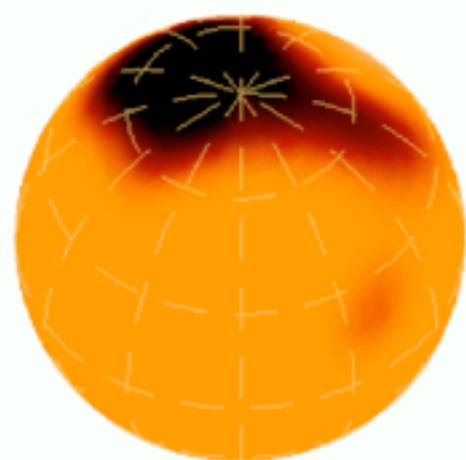

SES Phase vs. Date diagram: each dot is one observation

$\phi = 0.00$

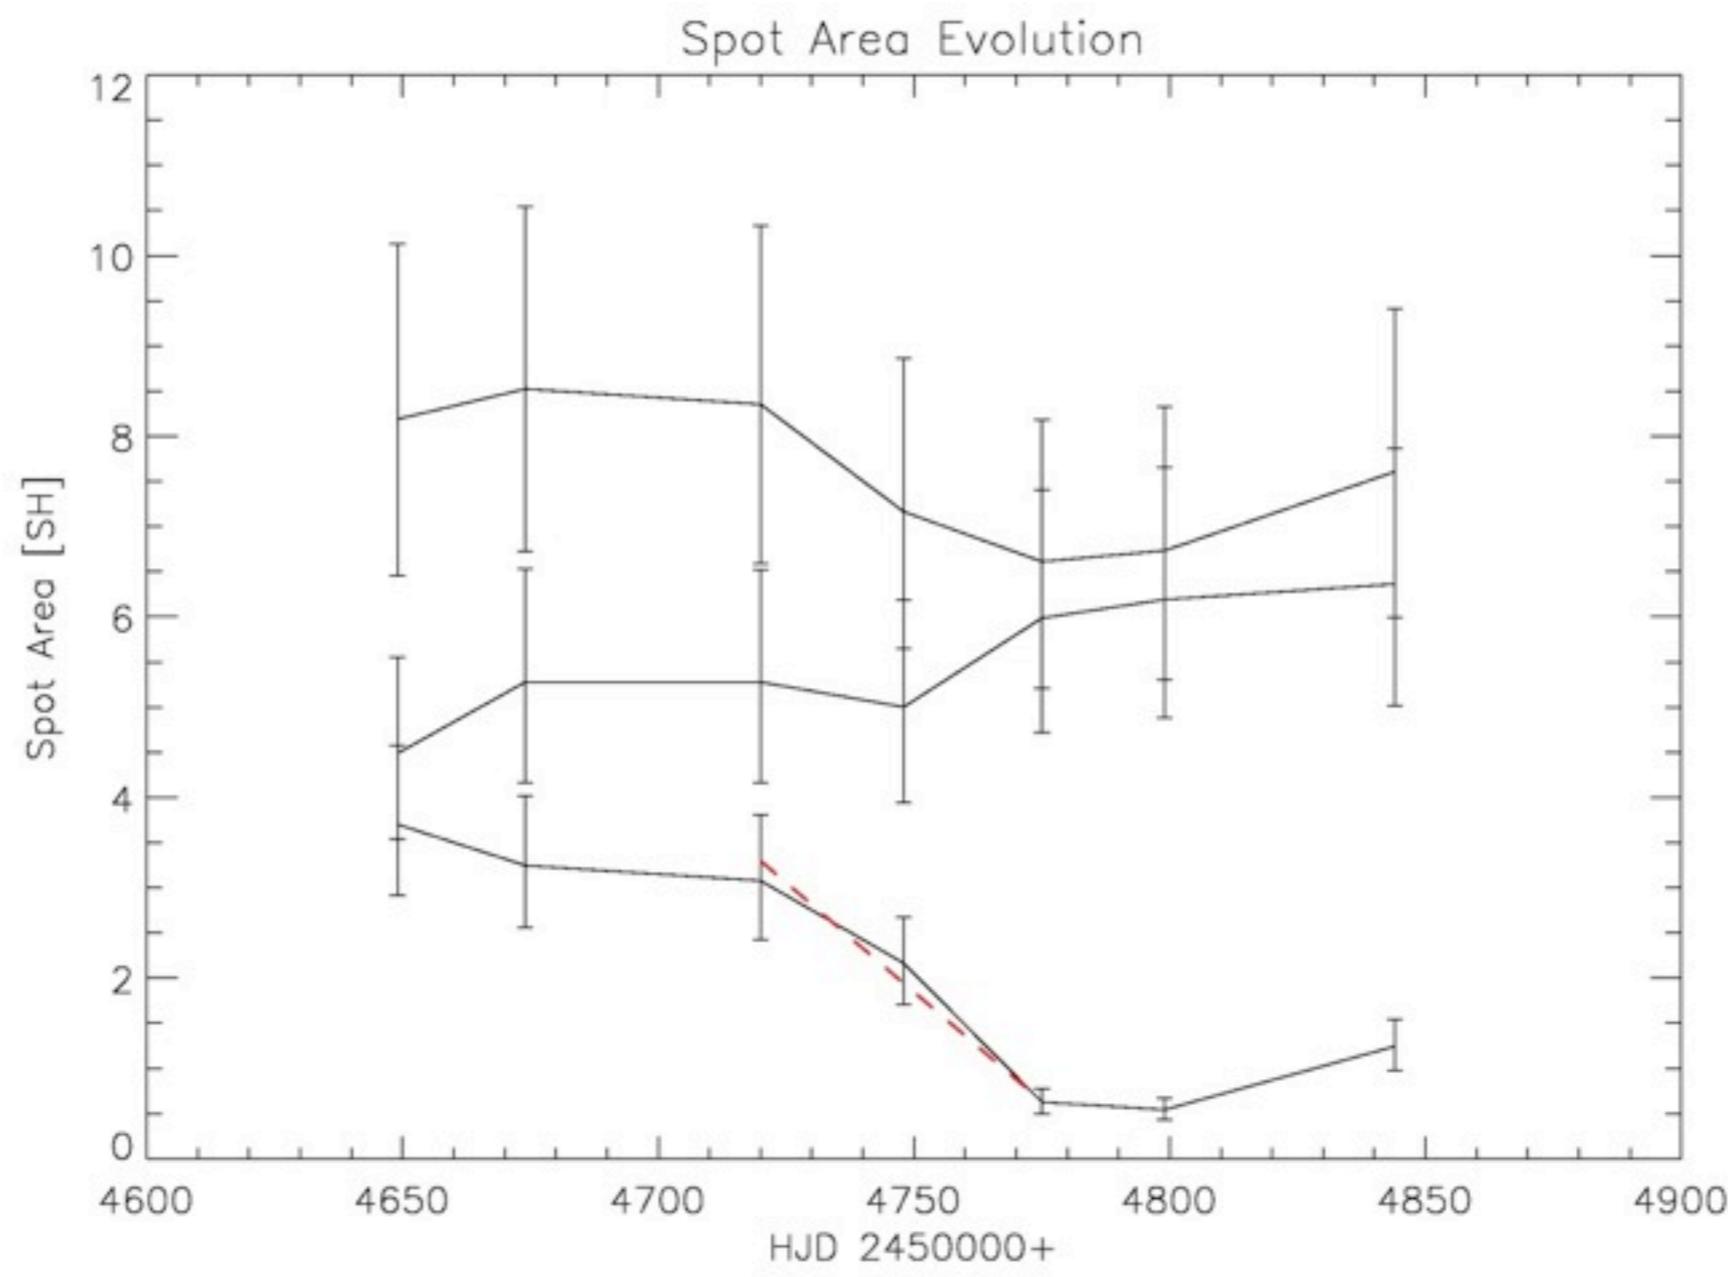

$\phi = 0.25$

$\phi = 0.50$

$\phi = 0.75$

Time series Doppler images: observations of spot evolution

Observations of a decaying spot - estimate for a spot decay law
